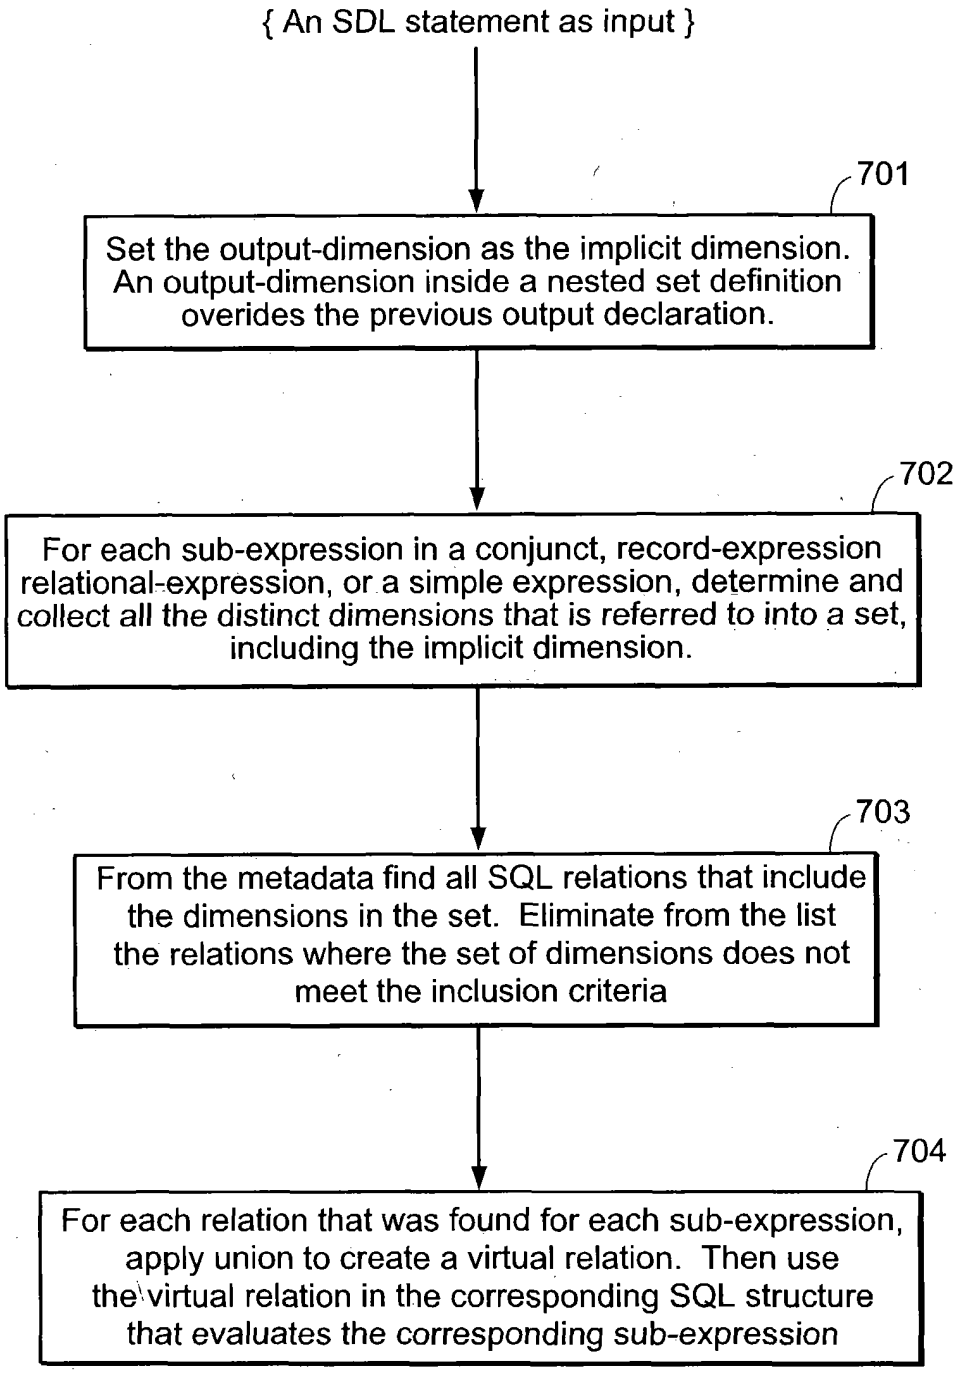
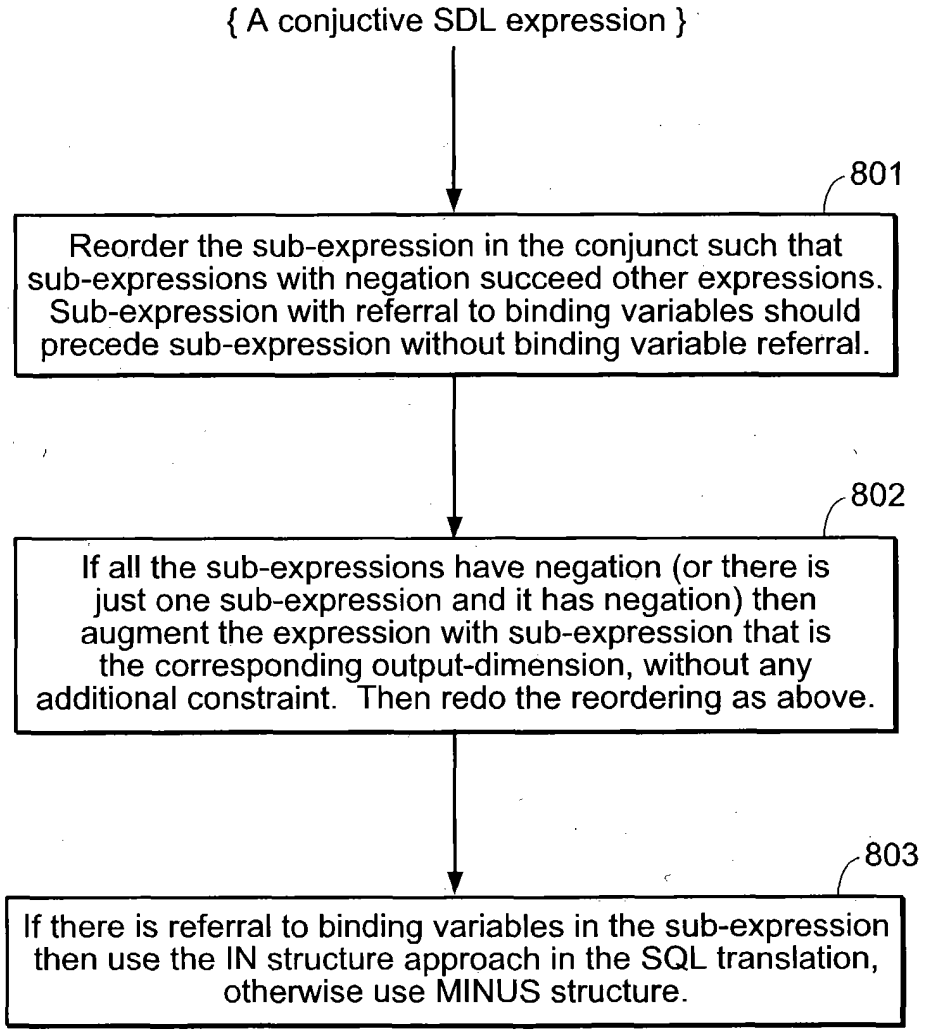
604

FIG. 6



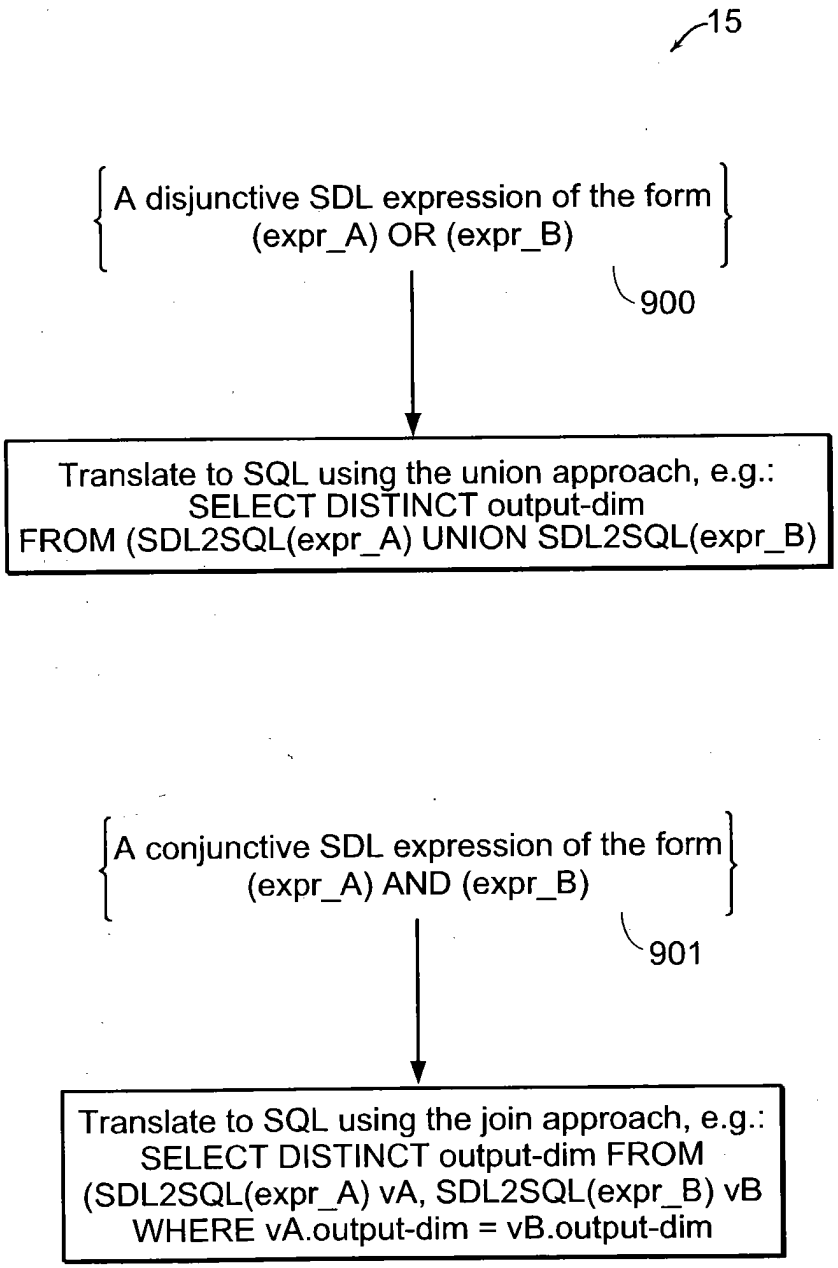
{ An SDL statement as input }
701
Set the output-dimension as the implicit dimension. An output-dimension inside a nested set definition overides the previous output declaration.
702
For each sub-expression in a conjunct, record-expression relational-expression, or a simple expression, determine and collect all the distinct dimensions that is referred to into a set, including the implicit dimension.
703
From the metadata find all SQL relations that include the dimensions in the set. Eliminate from the list the relations where the set of dimensions does not meet the inclusion criteria
704
For each relation that was found for each sub-expression, apply union to create a virtual relation. Then use the virtual relation in the corresponding SQL structure that evaluates the corresponding sub-expression

FIG. 7



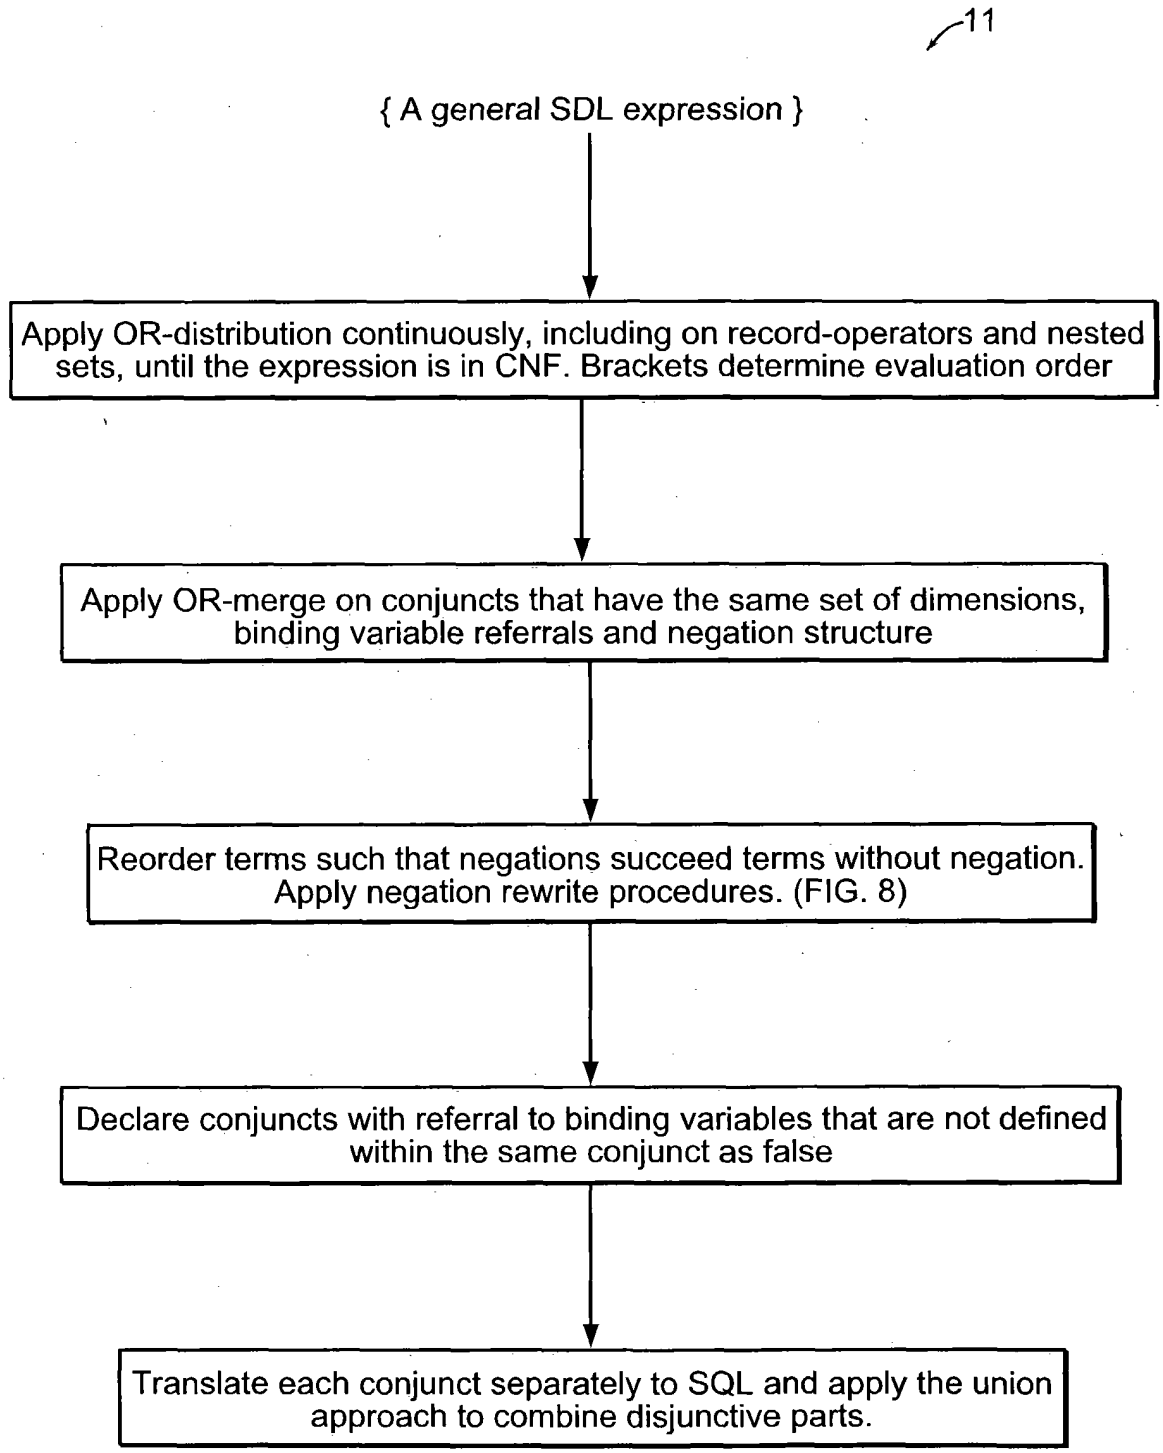
{ A conjuctive SDL expression }
801
Reorder the sub-expression in the conjunct such that sub-expressions with negation succeed other expressions. Sub-expression with referral to binding variables should precede sub-expression without binding variable referral.
802
If all the sub-expressions have negation (or there is just one sub-expression and it has negation) then augment the expression with sub-expression that is the corresponding output-dimension, without any additional constraint. Then redo the reordering as above.
803
If there is referral to binding variables in the sub-expression then use the IN structure approach in the SQL translation, otherwise use MINUS structure.

FIG. 8



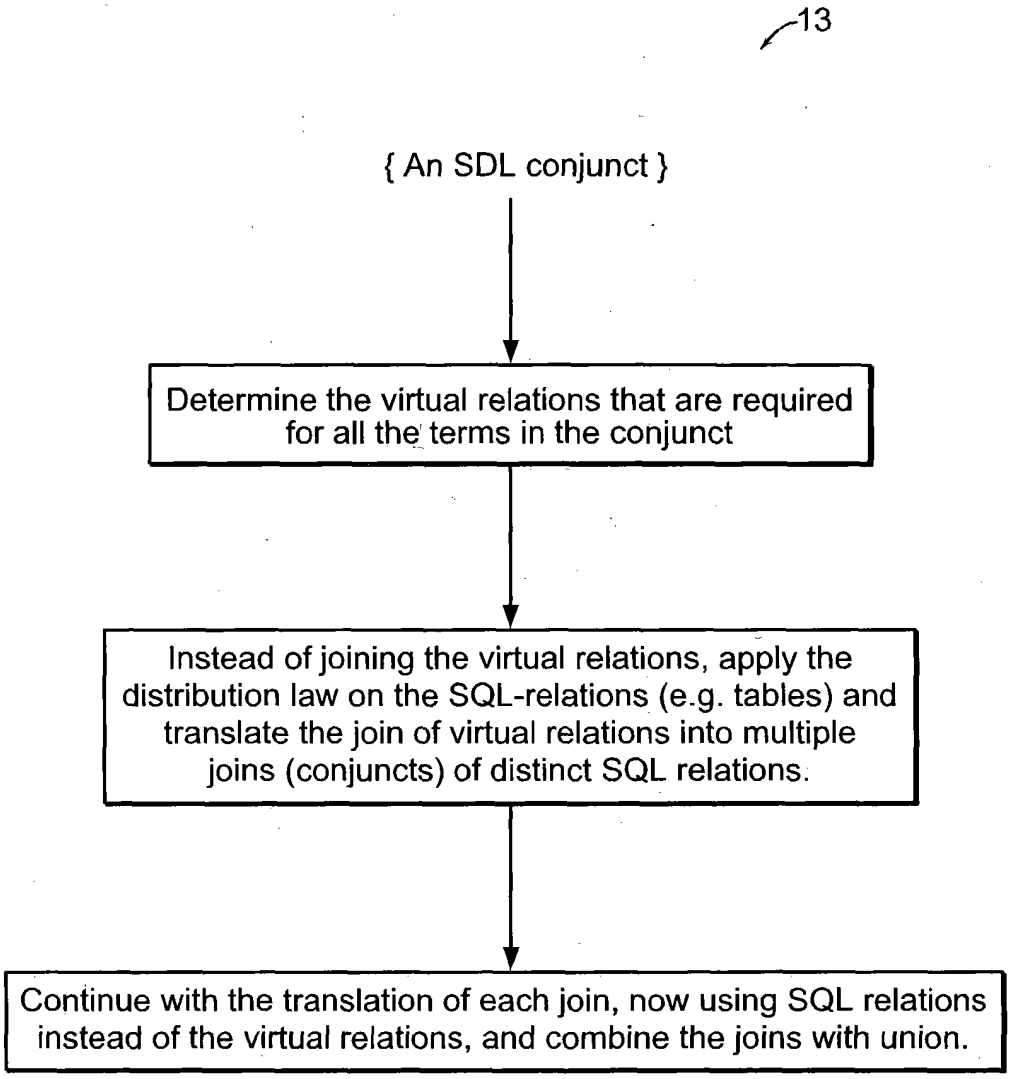
15
A disjunctive SDL expression of the form (expr_A) OR (expr_B)
900
Translate to SQL using the union approach, e.g.: SELECT DISTINCT output-dim FROM (SDL2SQL(expr_A) UNION SDL2SQL(expr_B)
A conjunctive SDL expression of the form (expr_A) AND (expr_B)
901
Translate to SQL using the join approach, e.g.: SELECT DISTINCT output-dim FROM (SDL2SQL(expr_A) vA, SDL2SQL(expr_B) vB WHERE vA.output-dim = vB.output-dim

FIG. 9



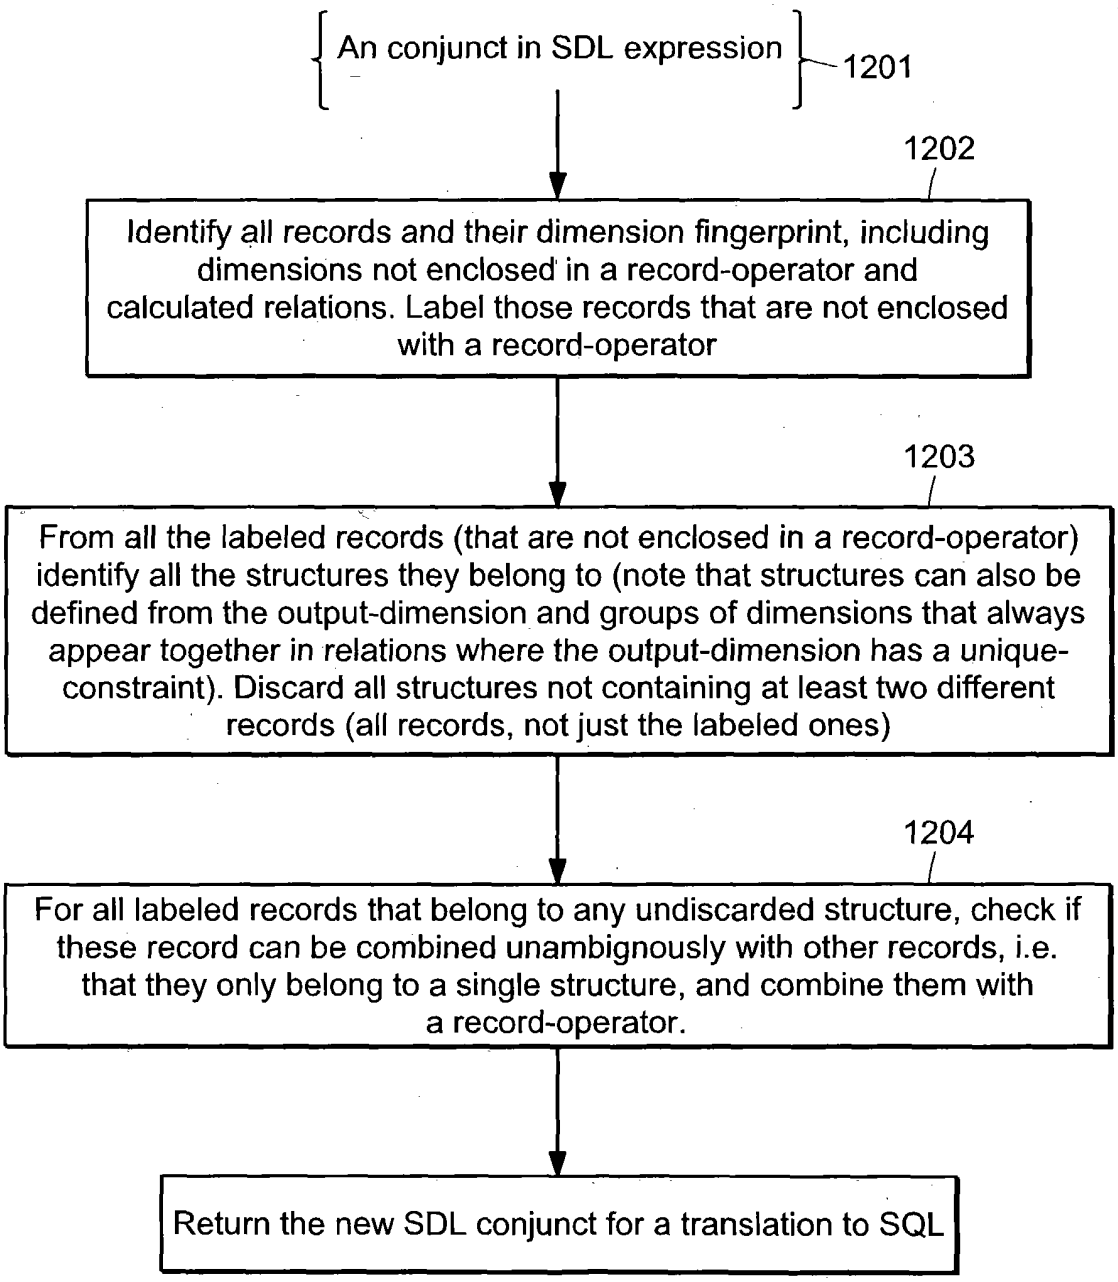
11
{ A general SDL expression }
Apply OR-distribution continuously, including on record-operators and nested sets, until the expression is in CNF. Brackets determine evaluation order
Apply OR-merge on conjuncts that have the same set of dimensions, binding variable referrals and negation structure
Reorder terms such that negations succeed terms without negation. Apply negation rewrite procedures. (FIG. 8)
Declare conjuncts with referral to binding variables that are not defined within the same conjunct as false
Translate each conjunct separately to SQL and apply the union approach to combine disjunctive parts.

FIG. 10



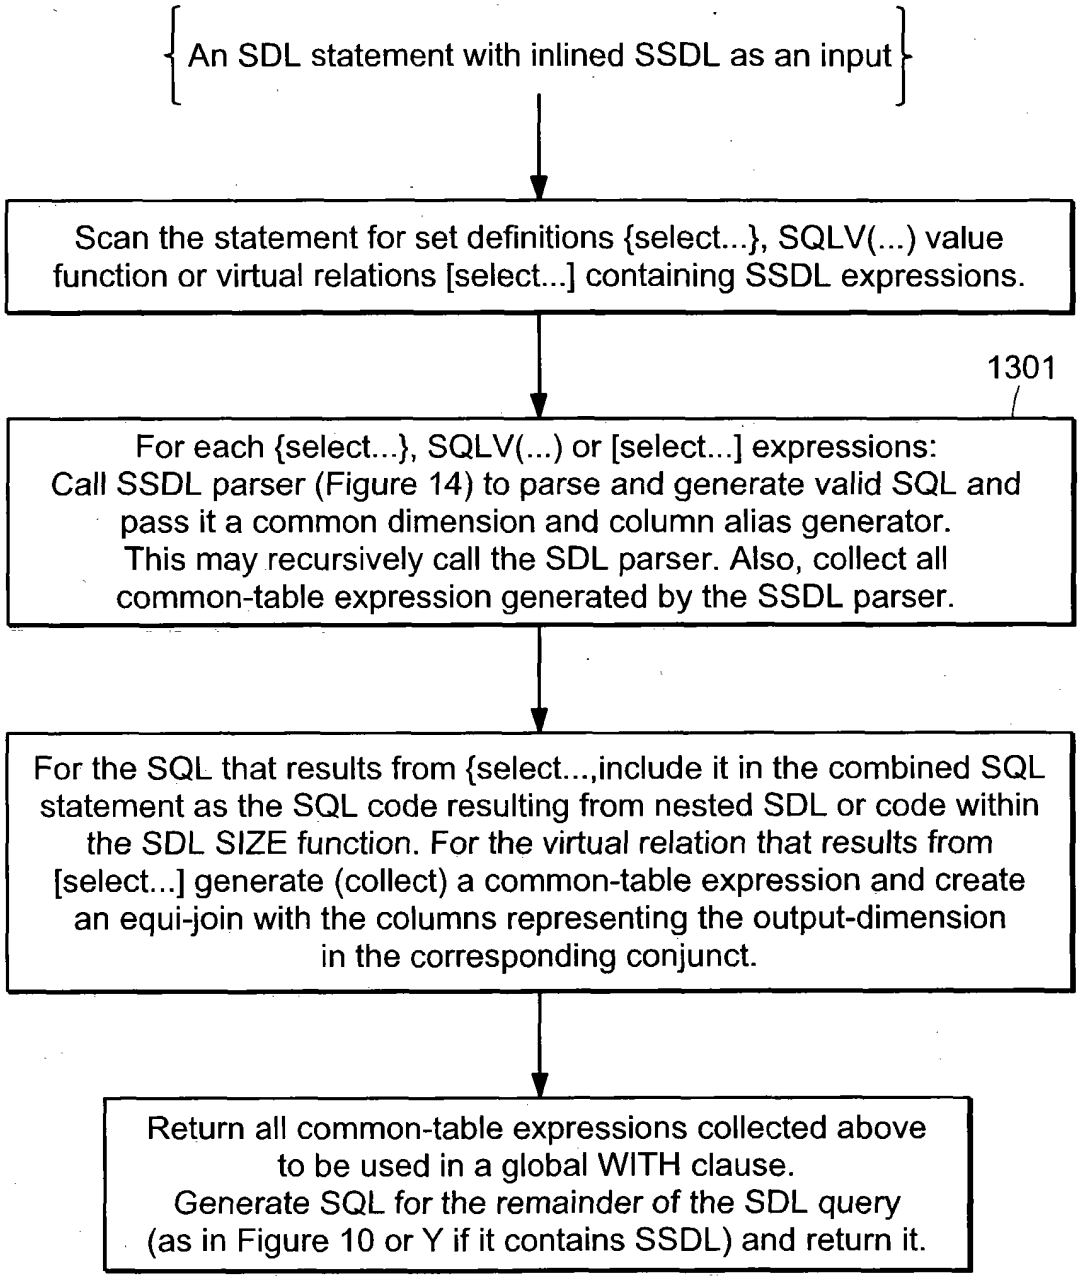
13
{ An SDL conjunct }
Determine the virtual relations that are required for all the terms in the conjunct
Instead of joining the virtual relations, apply the distribution law on the SQL-relations (e.g. tables) and translate the join of virtual relations into multiple joins (conjuncts) of distinct SQL relations.
Continue with the translation of each join, now using SQL relations instead of the virtual relations, and combine the joins with union.

FIG. 11



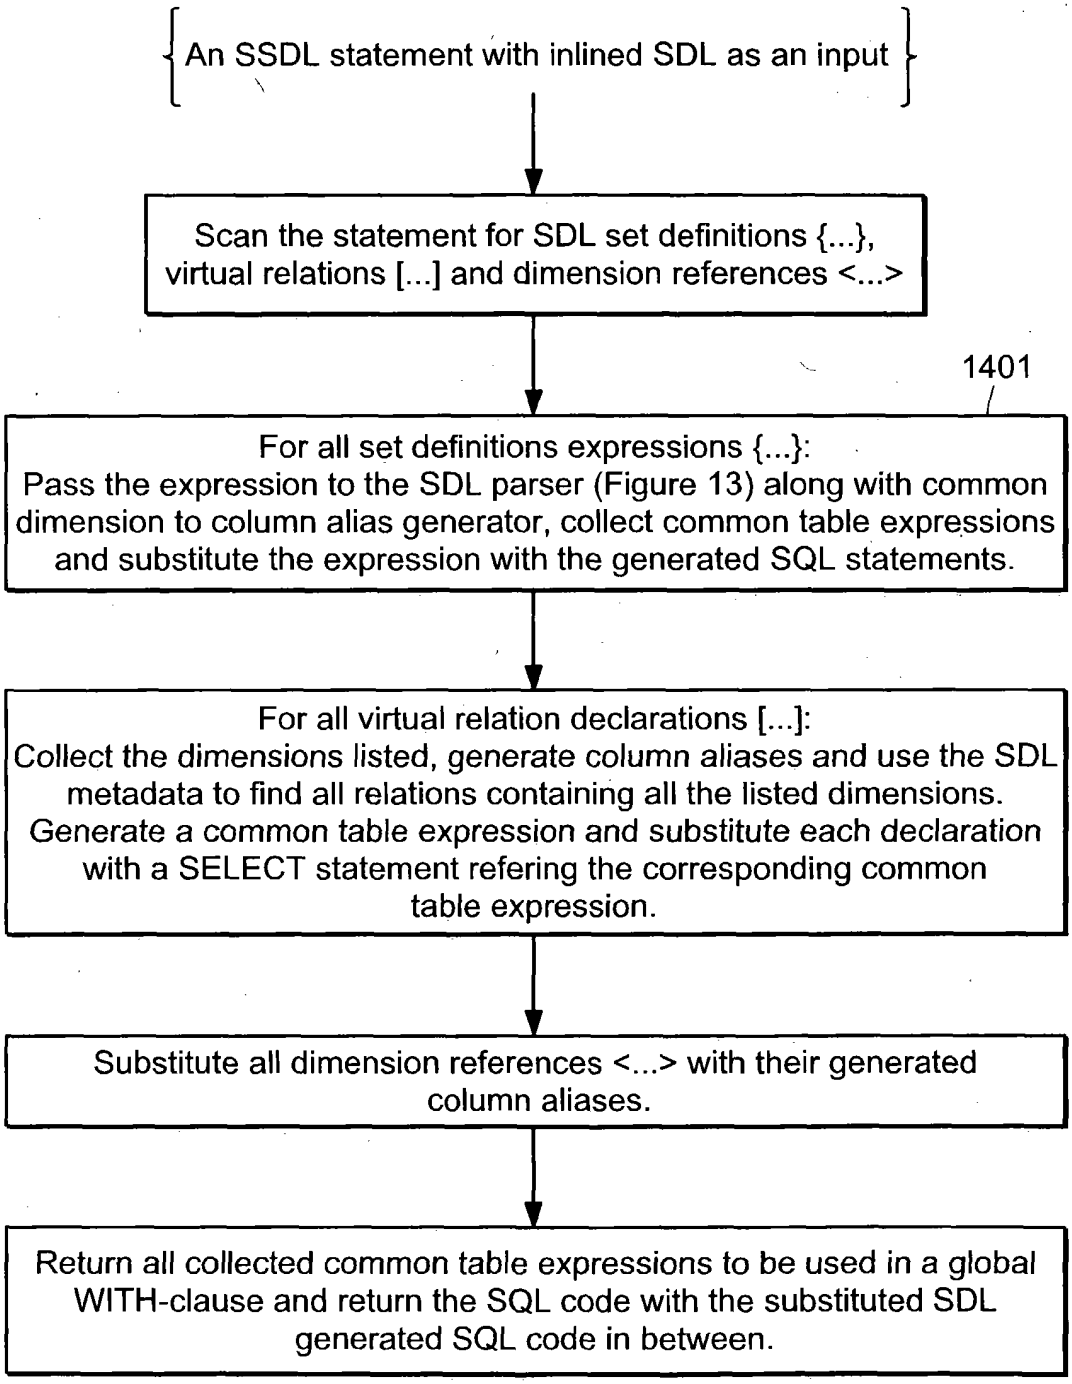
An conjunct in SDL expression
1201
1202
Identify all records and their dimension fingerprint, including dimensions not enclosed in a record-operator and calculated relations. Label those records that are not enclosed with a record-operator
1203
From all the labeled records (that are not enclosed in a record-operator) identify all the structures they belong to (note that structures can also be defined from the output-dimension and groups of dimensions that always appear together in relations where the output-dimension has a unique-constraint). Discard all structures not containing at least two different records (all records, not just the labeled ones)
1204
For all labeled records that belong to any undiscarded structure, check if these record can be combined unambignously with other records, i.e. that they only belong to a single structure, and combine them with a record-operator.
Return the new SDL conjunct for a translation to SQL

FIG. 12



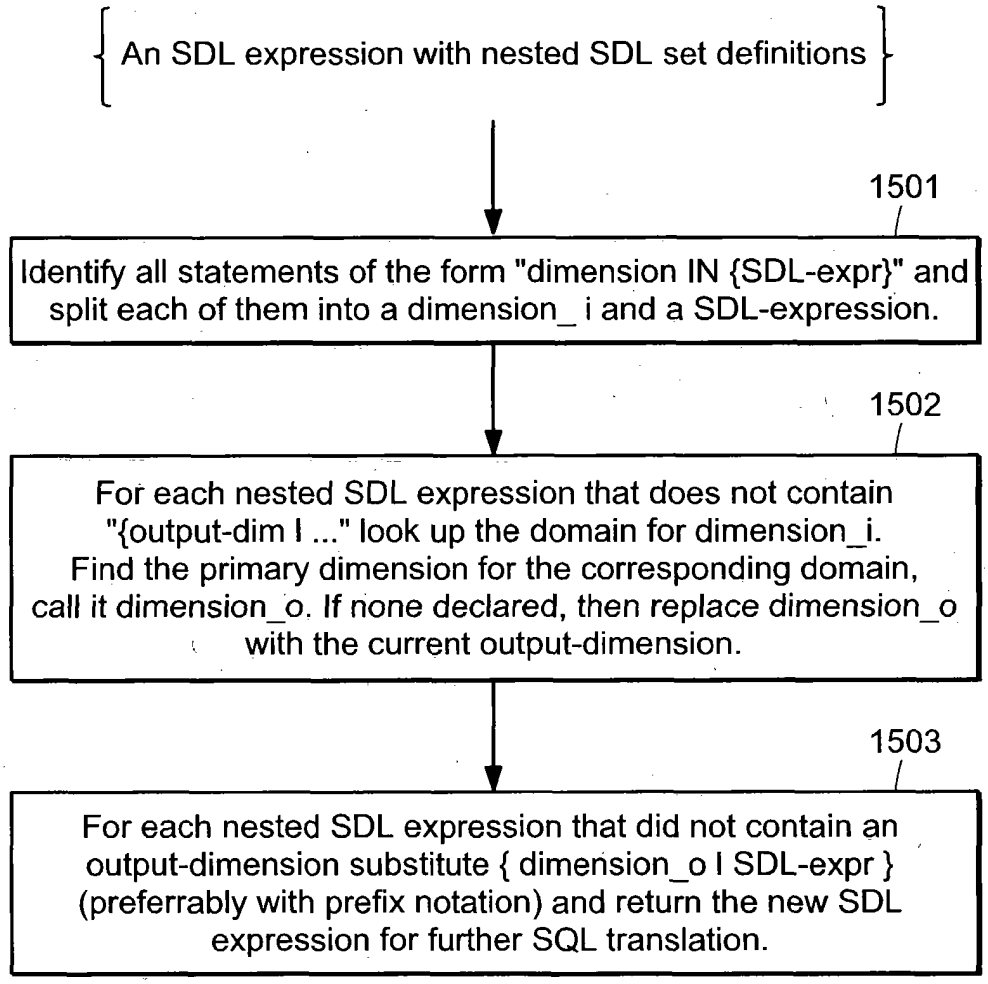
An SDL statement with inlined SSDL as an input
Scan the statement for set definitions {select...}, SQLV(...) value function or virtual relations [select...] containing SSDL expressions.
1301
For each {select...}, SQLV(...) or [select...] expressions:
Call SSDL parser (Figure 14) to parse and generate valid SQL and pass it a common dimension and column alias generator.
This may recursively call the SDL parser. Also, collect all common-table expression generated by the SSDL parser.
For the SQL that results from {select...,include it in the combined SQL statement as the SQL code resulting from nested SDL or code within the SDL SIZE function. For the virtual relation that results from [select...] generate (collect) a common-table expression and create an equi-join with the columns representing the output-dimension in the corresponding conjunct.
Return all common-table expressions collected above to be used in a global WITH clause.
Generate SQL for the remainder of the SDL query (as in Figure 10 or Y if it contains SSDL) and return it.

FIG. 13



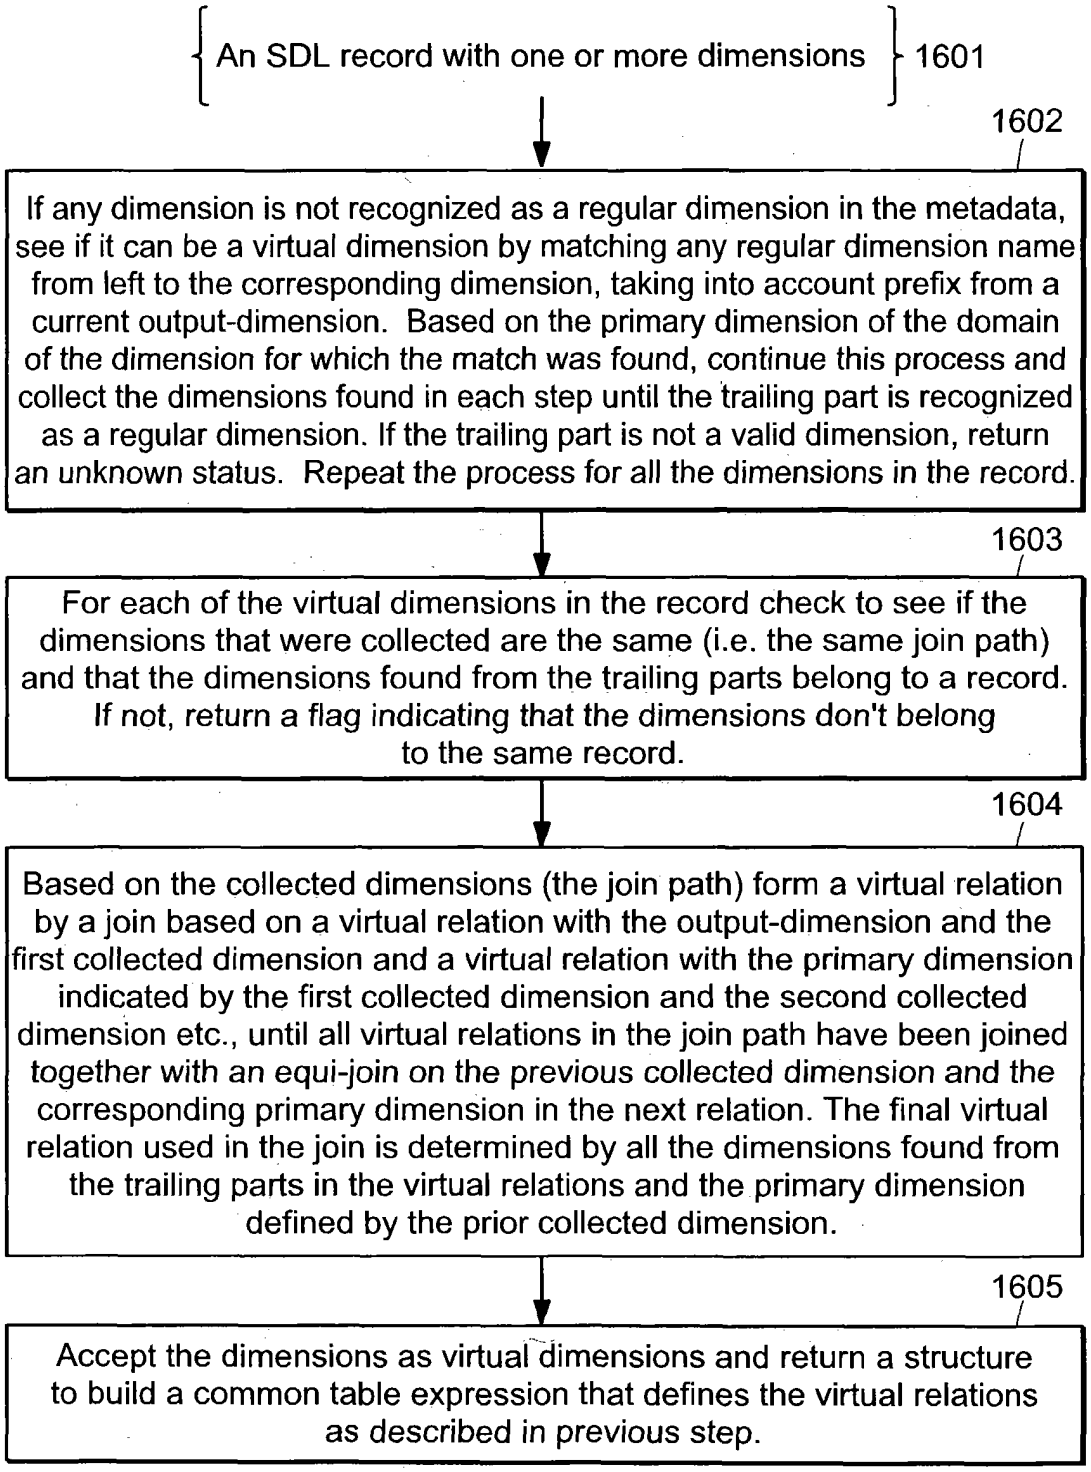
An SSDL statement with inlined SDL as an input
Scan the statement for SDL set definitions {...}, virtual relations [...] and dimension references <...>
1401
For all set definitions expressions {...}:
Pass the expression to the SDL parser (Figure 13) along with common dimension to column alias generator, collect common table expressions and substitute the expression with the generated SQL statements.
For all virtual relation declarations [...]:
Collect the dimensions listed, generate column aliases and use the SDL metadata to find all relations containing all the listed dimensions. Generate a common table expression and substitute each declaration with a SELECT statement refering the corresponding common table expression.
Substitute all dimension references <...> with their generated column aliases.
Return all collected common table expressions to be used in a global WITH-clause and return the SQL code with the substituted SDL generated SQL code in between.

FIG. 14



An SDL expression with nested SDL set definitions
1501
Identify all statements of the form "dimension IN {SDL-expr}" and split each of them into a dimension_ i and a SDL-expression.
1502
For each nested SDL expression that does not contain "{output-dim I ..." look up the domain for dimension_i. Find the primary dimension for the corresponding domain, call it dimension_o. If none declared, then replace dimension_o with the current output-dimension.
1503
For each nested SDL expression that did not contain an output-dimension substitute { dimension_o I SDL-expr } (preferrably with prefix notation) and return the new SDL expression for further SQL translation.

FIG. 15



An SDL record with one or more dimensions
1601
1602
If any dimension is not recognized as a regular dimension in the metadata, see if it can be a virtual dimension by matching any regular dimension name from left to the corresponding dimension, taking into account prefix from a current output-dimension. Based on the primary dimension of the domain of the dimension for which the match was found, continue this process and collect the dimensions found in each step until the trailing part is recognized as a regular dimension. If the trailing part is not a valid dimension, return an unknown status. Repeat the process for all the dimensions in the record.
1603
For each of the virtual dimensions in the record check to see if the dimensions that were collected are the same (i.e. the same join path) and that the dimensions found from the trailing parts belong to a record. If not, return a flag indicating that the dimensions don't belong to the same record.
1604
Based on the collected dimensions (the join path) form a virtual relation by a join based on a virtual relation with the output-dimension and the first collected dimension and a virtual relation with the primary dimension indicated by the first collected dimension and the second collected dimension etc., until all virtual relations in the join path have been joined together with an equi-join on the previous collected dimension and the corresponding primary dimension in the next relation. The final virtual relation used in the join is determined by all the dimensions found from the trailing parts in the virtual relations and the primary dimension defined by the prior collected dimension.
1605
Accept the dimensions as virtual dimensions and return a structure to build a common table expression that defines the virtual relations as described in previous step.
